Livedoid vasculitis is a rare variant of vasculitis. We describe an algorithm to treat refractory livedoid vasculitis and to guide treatment decisions. A chart review was conducted of all patients diagnosed with a vasculitis at the University of North Carolina from 2004 to 2009. Inclusion criteria were that all patients had biopsy-proven livedoid vasculitis. All patients had failure to respond to standard therapy for vasculitis, and were treated with cyclosporine and oral glucocorticoids. Patients were treated with either cyclosporine or mycophenolate. Main outcome measures were overall survival and disease activity. Sixteen patients met criteria for inclusion. There were eight males and eight females. Mean age was 48 years (range: 33-66 years). The most common presentation was ulcers and purpura, followed by mononeuritis multiplex. Mean duration of disease was 27 months. The most common sites of involvement were lower extremities and toes. One patient developed myelofibrosis. One patient with antiphospholipid antibody syndrome had severe thrombocytopenia. Two patients died of renal failure, and one patient died of massive gastrointestinal bleeding. One patient developed progressive multifocal leukoencephalopathy. After a mean of 3.2 years (range: 0.5-7 years), patient and disease activity data were available for all patients. Of 10 patients who had not achieved remission, five patients achieved remission after cyclosporine and three patients with mycophenolate. Of six patients who had not responded to cyclosporine 82157476af
